### Abstract

A survey of the knowledge on edible wild plants in Campania (Italy) is presented. The checklist is based not only on literature data but also on unpublished results coming from archives of the authors. 639 records of alimentary uses related to 198 taxa are listed. Asteraceae, Lamiaceae, Brassicaceae and Rosaceae are the most represented families. The predominant biological forms are Hemicryptophytes, Terophytes and Phanerophytes. The parts of plant used as food mainly include leaves and aerial parts, followed by flowers, fruits and seeds, whereas roots and other underground parts are less frequently used. Many species are consumed in salads or soups and served in mixtures. The alimentary uses of most species are widespread in Campania, but the uses of 28 species are strictly linked to limited territories.

**Keyword:** Ethnobotany, Campania, edible wild plants

### Riassunto

Viene presentata una rassegna delle conoscenze sulle piante selvatiche commestibili in Campania (Italia). La checklist non si basa solo su dati di letteratura ma anche su risultati inediti provenienti dagli archivi degli autori. Sono stati elencati 639 record di usi alimentari relativi a 198 taxa. Asteraceae, Lamiaceae, Brassicaceae e Rosaceae sono le famiglie più rappresentate. Le forme biologiche predominanti sono: Emicriptofite, Terofite e Fanerofite. Le parti delle piante utilizzate come cibo sono principalmente foglie e parti aeree delle piante, seguite da fiori, frutti e semi, mentre radici e altre parti sotterranee sono usate meno frequentemente. Molte specie si consumano in insalate o zuppe e si usano in

combinazione con altre. La maggior parte delle specie sono adoperate in tutto il territorio Campano, ma gli usi di 28 specie sono strettamente legati a territori circoscritti.

**Parole chiave:** Etnobotanica, Campania, piante selvatiche commestibili

## Introduction

The use of edible wild plants in southern Europe is still lively, albeit on decline. Throughout the Mediterranean region these plants played a role in the surviving strategy of rural communities for centuries, and there is a diffused awareness that such a heritage should be preserved as it represents a source of untapped information about numerous neglected species (Vanzani et al. 2011).

Wild food plants differ among regions of the Mediterranean basin. Yet, as a general rule, wild greens are largely consumed, having a seasonal usage (Hadjichambis et al. 2008). Often, edible wild plants are weeds, considered noxious to crop cultivation. For this reason, they are controlled by using herbicides and mechanical eradication, even though weeds also play important ecological roles, as sources of biodiversity, as key components of seminatural edge habitats and preventing soil erosion (Turner et al. 2011). The first report on Italian wild edible plants dates back to 1980s (Aliotta 1987). Recent research confirms that in Italy, and particularly in southern regions, numerous wild edible species are still commonly consumed. In Apulia more than 220 wild herbaceous species are used as food

(Biscotti et al. 2018), whereas in Sicily about 300 native edible wild plants were identified in a recent study, based on a review of the extant literature and on recent field investigations (Pasta et al. 2020).

As far as concerns the Campania Region, numerous ethnobotanical reports have been published in the last decades, frequently including information on local uses of edible wild plants. The present study provides the first compilation of ethnobotanical data collected in this territory, aiming to delineate a comprehensive picture of the geographical distribution of these data. This contribution could promote future field investigation, focusing the attention on the Campanian territories where information on edible wild plants is scanty or worse lacking.

## Material and Methods

The list of the edible wild plants of Campania was based on a critical review of recent literature available on this topic, namely: De Natale et al. (2009); De Natale and Pollio (2007); De Rosa et al. (2008); Di Novella et al. (2012); Guarino et al. (2008); La Palometa and Grieco (2003); Mautone et al. (2019); Menale et al. (2016); Menale and Muoio (2014); Motti et al. (2009); Motti and Motti (2017); Salerno and Guarnera (2008);

Savo et al. (2015); Savo et al. (2019); Scherrer et al. (2015).

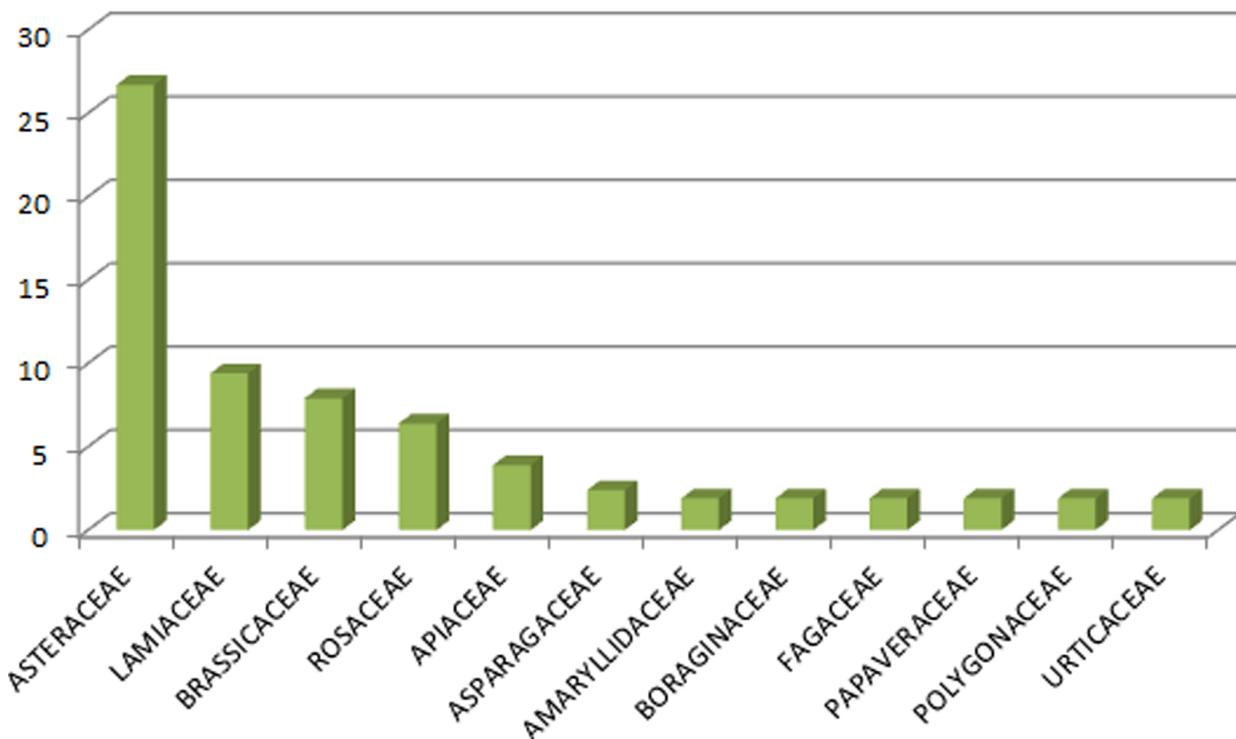

The recent ethnobotanical bibliography was integrated with information coming from the archives of Antonino De Natale (ADN) and Bruno Menale (BM), that further includes unpublished data (u.d.), collected during fieldworks carried out in different areas of the Campania region. As basic references from neighboring regions we considered: Biscotti et al. (2018), for Apulia; Menale et al. (2006), for Molise; Guarnera et al. (2006), for Basilicata; Passalacqua et al. (2006), Nebel et al. (2006), for Calabria; Pasta et al. (2020), for Sicily.

The checklist of edible wild plants reports for

plant used, and Food uses are the other fields included in the check list, that provide an updated information about the uses of edible wild plants in Campania. Life form and chorotypes were recorded in keeping with Pignatti (1982). The taxa are listed in alphabetical order according to their scientific name.

## Results

In the Supplementary Table S1 we list 639 records of alimentary uses, that are related to 198 different taxa. The most represented families are Asteraceae (25.2%), Lamiaceae (9.4%), Brassicaceae (7.9%) and Rosaceae (6.4%) (Fig. 1).

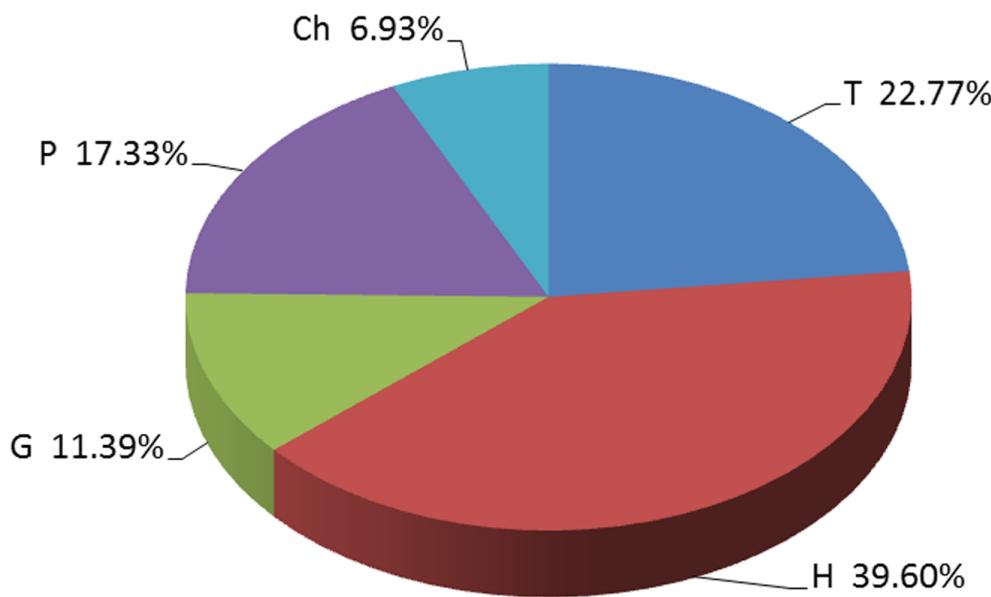

**Figure 1:** Families of food plants used in Campania. The families with a score < 2% are not represented in the figure.

each taxon the scientific name and the plant family, as reported by Pignatti (2017-2018). Local names, Province, Locality, Part of the

fruits and flowers. The hypogean organs, either roots or bulbs are less represented. On a gastronomic level, plants are mainly consumed in salads or soups, frequently mixing more species (as in the case of the very frequently cited "minestra maritata", or

"minestra terrana"). Plants and gastronomic uses common to different territory of the region account for more than 50% of the total, but for 26 plants (28%) an alimentary use was reported only for small territories (Table 1).

## Discussion and Conclusion

The data collected in this survey show a non-homogeneous distribution of knowledge on wild edible plants in Campania. The information is mainly concentrated over Naples and Salerno provinces, whereas it is still scanty in the remaining parts of the region (Fig. 4). It is noteworthy the occurrence of food taxa belonging to Lamiaceae and Rosaceae that ranks second and third, after Asteraceae. The prevalence of species belonging to the latter is common

to the rest of Italian regions, whereas Rosaceae are more frequently used in Northern Italy (Biscotti et al. 2018). The high frequency of Lamiaceae is due to their large use as flavoring spices.

The frequency of biological forms shows a prevalence of Hemicryptophytes and Terophytes, together with a relevant occurrence of Phanerophytes, that could be related to the widespread occurrence in Campania of hillslopes, where woody plants

**Figure 4:** Distribution of ethno-alimentary information in Campania region during the XX and XXI Century. Points (red circle) designate local information (territories up to 10 km). Colored areas are related to data generically attributed to large territories.

represent a relevant proportion of species spectrum.

The predominance of food plants belonging to Cosmopolitan and Eurasiacal chorological groups over the Mediterranean ones is another remarkable trait of alimurgic flora of Campania that could be explained under an ecological perspective.

Among the species whose edible utilization is restricted to a single or few locality, *Centaurea calcitrapa* is worthy of mention. The aerial parts of the plant are boiled and consumed in Sicily (Lentini and Venza 2007), and in Cyprus (Della et al. 2006), and a similar use in Campania is reported only for three municipalities of the Benevento Province.

An interesting trait showed by the Picentini edible flora (Savo et al. 2019) is the use of some potentially toxic plant species (i.e., *Pteridium aquilinum* and *Taxus baccata*). The presence of these species in the list of edible plants could represent a trace of a "famine diet" exploited by local people in times of food shortage.
